Rare-group recall under training-label contamination

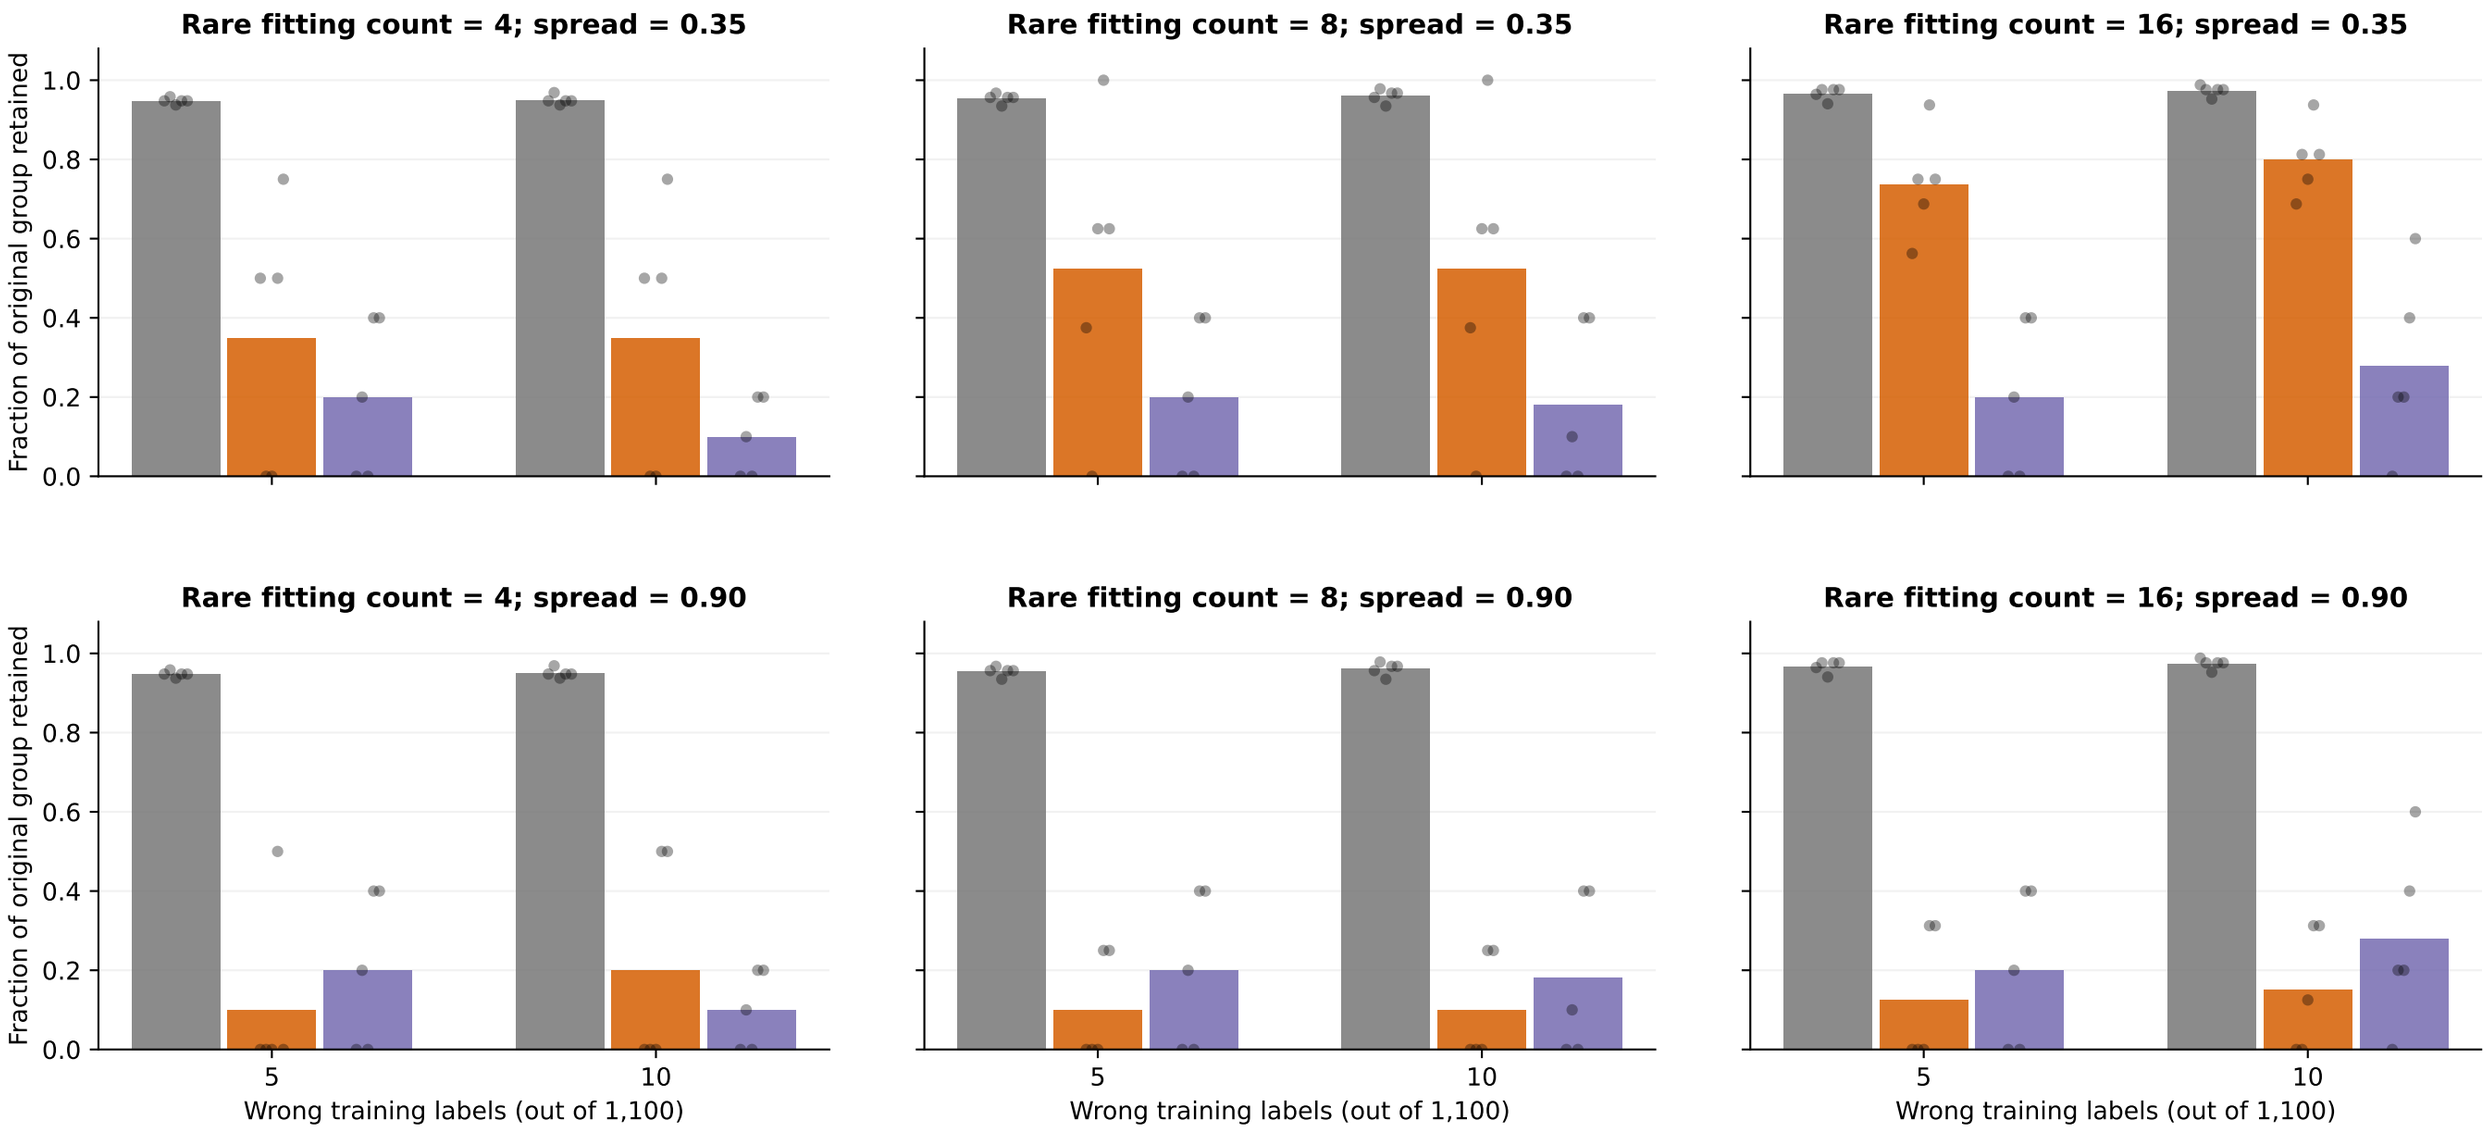

Same feature rows and true groups across noise levels. Lines: five-seed means; faint points: seeds.

RF, 100 trees; calibration FPR = 0.05 for every model. Actual test FPR varies and is reported separately.

Which originals did default AW removal retain?

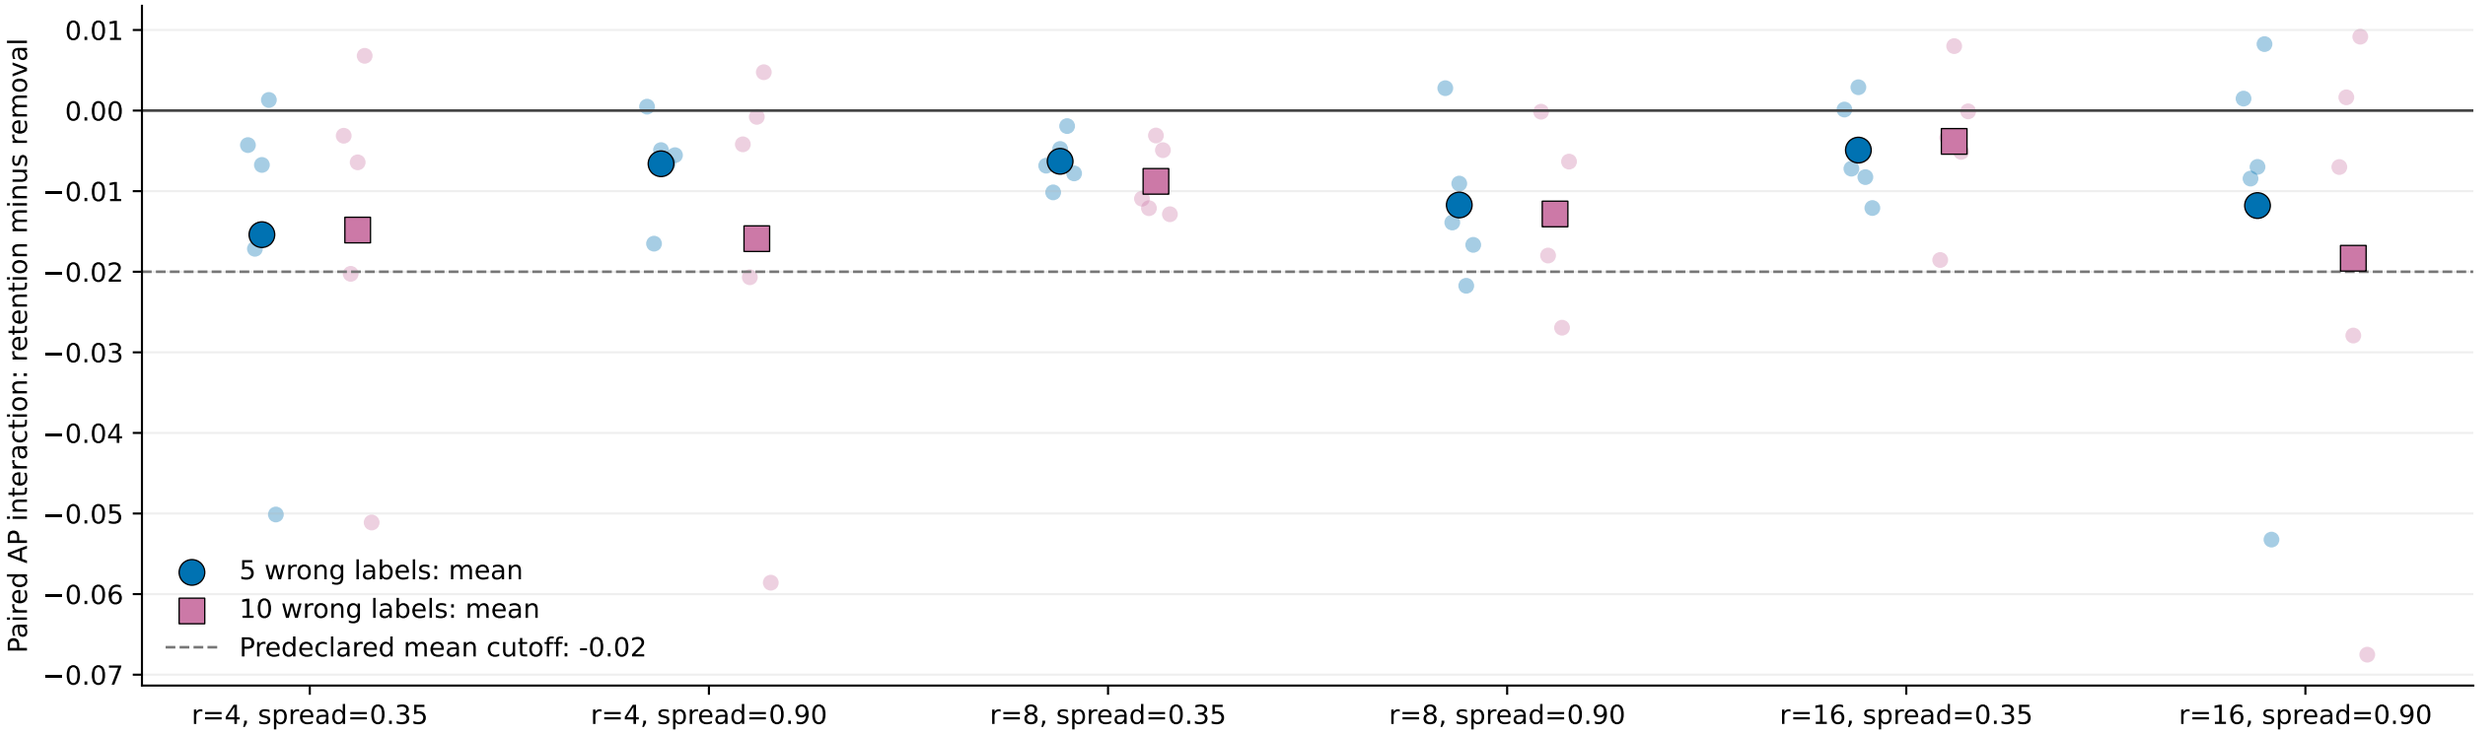

Bars: five-seed means; dots: individual seeds. Ground-truth identities are evaluator-only.

Retained mislabeled originals are one diagnostic; synthetic parent exposure and final training counts are saved separately.

Did retention lose more AP under contamination?

Interaction = (retention noisy - clean AP) - (removal noisy - clean AP)

Below zero: retention lost more AP. Markers: five-seed means; faint dots: seeds. The full screen also requires rare-recall and FPR conditions.
